

Network automation at scale

Up and running in 60 minutes

Mircea Ulinic
Cloudflare, London

NANOG 69 Washington, D.C.
February 2017

Why us?

- How big?
 - Four+ million zones/domains
 - Authoritative for ~40% of Alexa top 1 million
 - 43+ billion DNS queries/day
 - Second only to Verisign
- 100+ anycast locations globally
 - 50 countries (and growing)
 - Many hundreds of network devices

To automate, I have to learn Python or another programming language.

To automate, I have to learn Python or another programming language.

WRONG!

Prerequisites

- No programming skills required (but very welcome)!
- Basic system ops
- Networking (of course)
- Basic [YAML](#) & [Jinja](#) understanding
(6 simple rules is all you need for the beginning)

Agenda

- Meet the tools
- Install the tools
- Configure Vagrant VMs (demo only)
- Configure SaltStack
- CLI syntax
- Configuration management
- Advanced topics

Meet the Tools

Live setup

- Access to a remote server

OR

- Vagrant + VM(s) from your favourite vendor(s)

NOTE: Vagrant is used for demo only!

The power of SaltStack can be seen when managing high number of real network devices!

Meet the Tools

Why Salt?

- Very scalable
- Concurrency
- Easily configurable & customizable
- Config verification & enforcement
- Periodically collect statistics
- Native caching and drivers for useful tools

Meet the Tools

Orchestration vs. Automation

Meet the Tools

Why Salt?

“

In SaltStack, speed isn't a byproduct, it is a design goal. SaltStack was created as an extremely fast, lightweight communication bus to provide the foundation for a remote execution engine.

SaltStack now provides orchestration, configuration management, event reactors, cloud provisioning, and more, all built around the SaltStack high-speed communication bus.

... + cross-vendor network automation from 2016.11 (Carbon)

”

<https://docs.saltstack.com/en/getstarted/speed.html>

Meet the Tools

Why NAPALM?

(Network Automation and Programmability Abstraction Layer with Multivendor support)

<https://github.com/napalm-automation>

NAPALM integrated in SaltStack

NETWORK AUTOMATION: NAPALM

Beginning with 2016.11.0, network automation is included by default in the core of Salt. It is based on the [NAPALM](#) library and provides facilities to manage the configuration and retrieve data from network devices running widely used operating systems such as: JunOS, IOS-XR, eOS, IOS, NX-OS etc. - see [the complete list of supported devices](#).

The connection is established via the `NAPALM proxy`.

In the current release, the following modules were included:

- `NAPALM grains` - Select network devices based on their characteristics
- `NET execution module` - Networking basic features
- `NTP execution module`
- `BGP execution module`
- `Routes execution module`
- `SNMP execution module`
- `Users execution module`
- `Probes execution module`
- `NTP peers management state`
- `SNMP configuration management state`
- `Users management state`

<https://docs.saltstack.com/en/develop/topics/releases/2016.11.0.html>

Install the tools

Install NAPALM

```
$ pip install napalm
```

See [Complete installation notes](#)

Install the tools

Install SaltStack

```
$ sudo apt-get install salt-master
```

```
$ sudo apt-get install salt-proxy
```

See [Complete installation notes](#)

Configure Vagrant

This assumes [Vagrant](#) and [VirtualBox](#) are already installed

Vagrantfile examples:

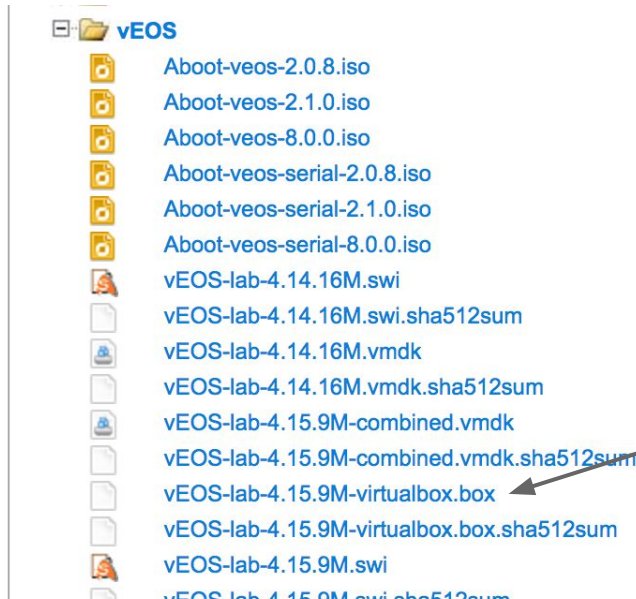

[What I use](#)
[Something simpler](#)

NOTE: skip this section if you are running in a real network environment (preferable)

Configure Vagrant

Download vEOS

Go to [Arista software download](#) (account required)

Select any `.box` file, but make sure that `VEOS_BOX` matches the name in the *Vagrantfile*.

Configure Vagrant

Download vSRX

```
$ vagrant box add juniper/ffp-12.1X47-D20.7-packetmode
==> box: Loading metadata for box 'juniper/ffp-12.1X47-D20.7-packetmode'
    box: URL: https://vagrantcloud.com/juniper/ffp-12.1X47-D20.7-packetmode
This box can work with multiple providers! The providers that it
can work with are listed below. Please review the list and choose
the provider you will be working with.

1) virtualbox
2) vmware_desktop

Enter your choice: 1
==> box: Adding box 'juniper/ffp-12.1X47-D20.7-packetmode' (v0.5.0) for provider: virtualbox
    box: Downloading:
https://atlas.hashicorp.com/juniper/boxes/ffp-12.1X47-D20.7-packetmode/versions/0.5.0/providers/virtualbox.box
==> box: Successfully added box 'juniper/ffp-12.1X47-D20.7-packetmode' (v0.5.0) for 'virtualbox'!
```

Configure Vagrant

Start Vagrant boxes

```
$ vagrant up vsrx
Bringing machine 'vsrx' up with 'virtualbox' provider...
==> vsrx: Setting the name of the VM: mirucha_vsr_x_1483551699725_41640
==> vsrx: Clearing any previously set network interfaces...
==> vsrx: Preparing network interfaces based on configuration...
    vsrx: Adapter 1: nat
    vsrx: Adapter 2: intnet
    vsrx: Adapter 3: intnet
    vsrx: Adapter 4: intnet
    vsrx: Adapter 5: intnet
==> vsrx: Forwarding ports...
    vsrx: 22 (guest) => 12202 (host) (adapter 1)
    vsrx: 830 (guest) => 12830 (host) (adapter 1)
    vsrx: 80 (guest) => 12280 (host) (adapter 1)
==> vsrx: Booting VM...
==> vsrx: Waiting for machine to boot. This may take a few minutes...
    vsrx: SSH address: 127.0.0.1:12202
    vsrx: SSH username: vagrant
    vsrx: SSH auth method: private key
    vsrx:
```

Configure SaltStack

New to Salt?

Pillar

Free-form data that can be used to organize configuration values or manage sensitive data, e.g.: interface details, NTP peers, BGP config...

written by the user, generally one file per device

Grains

data collected from the device, e.g.: device model, vendor, uptime, serial number etc.

Salt handles this, you don't need to do anything

Salt in 10 minutes: <https://docs.saltstack.com/en/latest/topics/tutorials/walkthrough.html>

Configure SaltStack

Master config

/etc/salt/master

```
file_roots:  
  base:  
    - /etc/salt/states  
pillar_roots:  
  base:  
    - /etc/salt/pillar
```

Environment name

Useful to have different environments: prod, qa, develop etc.

For the beginning, let's focus only on *file_roots* and *pillar_roots*. The others settings are more advanced features: <https://docs.saltstack.com/en/latest/ref/configuration/master.html>

[Complete salt master config file](#)

Configure SaltStack

Proxy config

/etc/salt/proxy

```
master: localhost
pki_dir: /etc/salt/pki/proxy
cachedir: /var/cache/salt/proxy
multiprocessing: False
mine_enabled: True
```

← **Very important!**

More about proxy minions: <https://docs.saltstack.com/en/latest/topics/proxyminion/index.html>

Configure SaltStack

Device *pillar*

Under the `pillar_roots` directory (as configured in `/etc/salt/master`):

`/etc/salt/pillar/device1.sls`

```
proxy:
  proxytype: napalm
  driver: junos
  host: hostname_or_ip_address
  username: my_username
  passwd: my_password
```

Mandatory

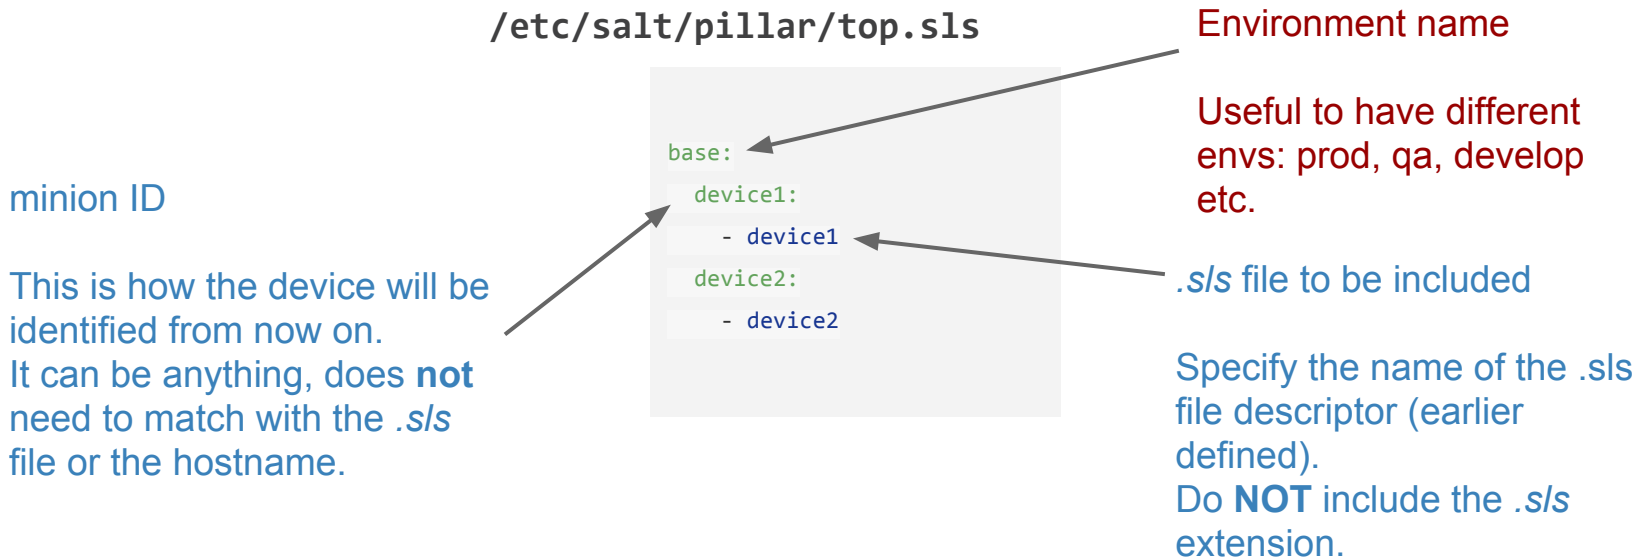

Choose between: junos,
eos, ios, iosxr, nxos, etc.
See the complete list.

Complete documentation at: <https://docs.saltstack.com/en/develop/ref/proxy/all/salt.proxy.napalm.html>

Configure SaltStack

The *top* file

Under the `pillar_roots` directory (as configured in `/etc/salt/master`):

Configure SaltStack

master systemd file (optional)

/etc/systemd/system/salt-master.service

```
[Unit]
Description=Salt Master
Requires=network.target
After=network.target

[Service]
Type=forking
PIDFile=/var/run/salt-master.pid
# ***NOTE*** the virtualenv here! Your location may vary!
ExecStart=/usr/bin/salt-master -d
Restart=on-failure
RestartSec=15

[Install]
WantedBy=multi-user.target
```

Configure SaltStack

proxy systemd file (optional)

/etc/systemd/system/salt-proxy@.service

```
[Unit]
Description=Salt proxy minion
After=network.target

[Service]
Type=simple
# ***NOTE*** the virtualenv here! Your location may vary!
ExecStart=/usr/bin/salt-proxy -l debug --proxyid %I
User=root
Group=root
Restart=always
RestartPreventExitStatus=SIGHUP
RestartSec=5

[Install]
WantedBy=default.target
```

Configure SaltStack

Start the salt-master

- With systemd:
 - `$ sudo systemctl start salt-master`
- Without systemd:
 - `$ sudo salt-master -d`  Start as daemon

Configure SaltStack

Start the salt-proxy processes

- With systemd:

- `$ sudo systemctl start salt-proxy@device1`
- `$ sudo systemctl start salt-proxy@device2`

minion ID

- Without systemd:

- `$ sudo salt-proxy -d --proxyid device1`
- `$ sudo salt-proxy -d --proxyid device2`

As configured in
the *top* file.

Configure SaltStack

Accept the proxies connection to the master

For each device, accept the minion key:

```
$ sudo salt-key -a device1
The following keys are going to be accepted:
Unaccepted Keys:
device1
Proceed? [n/Y] y
Key for minion device1 accepted.
```

minion ID

As configured in
the *top file*.

This is due to security reasons.

More about salt-key: <https://docs.saltstack.com/en/latest/ref/cli/salt-key.html>

NOTE: Accepting the minion keys can be automated as well.

Done!

You are now ready to automate your network!

Salt CLI syntax

Selecting the devices we need to run the command.

Targeting can be complex:

<https://docs.saltstack.com/en/latest/topics/targeting/>

```
$ sudo salt <target> <function> [<arguments>]
```

The diagram illustrates the Salt CLI syntax with a central command template. Three arrows point from explanatory text blocks to the components of the command: one from the URL above to the <target> placeholder, one from the 'Function name' block below to the <function> placeholder, and one from the 'Function arguments' block below to the [<arguments>] placeholder.

Function name, as specified in the module documentation.

For example if we need BGP-related commands, we'll look at the [BGP module](#).

Other examples: [dnsutil.A](#), [net.arp](#), [net.lldp](#), [net.traceroute](#) etc.

Function arguments, as specified in the module documentation.
Some functions do not require any arguments.

Salt CLI syntax

Examples

```
$ sudo salt 'edge*' net.traceroute 8.8.8.8
# execute traceroute on all devices whose minion ID starts with 'edge'

$ sudo salt -N NA transit.disable cogent
# disable Cogent in North-America

$ sudo salt -G 'os:junos' net.cli "show version"
# execute 'show version' on all devices running JunOS

$ sudo salt -C 'edge* and G@os:iosxr and G@version:6.0.2' net.arp
# get the ARP tables from devices whose ID starts with edge*, running IOS-XR 6.0.2

$ sudo salt -G 'model:MX480' probes.results
# retrieve the results of the RPM probes from all Juniper MX480 routers
```

→ 'NA' is a nodegroup:

<https://docs.saltstack.com/en/latest/topics/targeting/nodegroups.html>

Salt CLI syntax

Output example

Default output style: nested.

```
$ sudo salt edge01.iad01 net.arp
```

```
edge01.iad01:
```

```
out:
```

```
|_
```

```
age:
```

```
129.0
```

```
interface:
```

```
ae2.100
```

```
ip:
```

```
10.0.0.1
```

```
mac:
```

```
00:0f:53:36:e4:50
```

```
|_
```

```
age:
```

```
1101.0
```

```
interface:
```

```
xe-0/0/3.0
```

```
ip:
```

```
10.0.0.2
```

```
mac:
```

```
00:1d:70:83:40:c0
```

Salt CLI syntax

Outputters

```
$ salt --out=json edge01.iad01 net.arp
```

```
[
  {
    "interface": "ae2.100",
    "ip": "10.0.0.1",
    "mac": "00:0f:53:36:e4:50",
    "age": 129.0
  },
  {
    "interface": "xe-0/0/3.0",
    "ip": "10.0.0.2",
    "mac": "00:1d:70:83:40:c0",
    "age": 1101.0
  },
]
```

Using the **--out** optional argument, one can select the output format.

```
$ salt --out=yaml edge01.iad01 net.arp
```

```
edge01.iad01:
  comment: ''
  out:
    - age: 129.0
      interface: ae2.100
      ip: 10.0.0.1
      mac: 00:0f:53:36:e4:50
    - age: 1101.0
      interface: xe-0/0/3.0
      ip: 10.0.0.2
      mac: 00:1d:70:83:40:c0
```

```

Translated to *file_roots*,
as specified in the master config file - see slide #21.

E.g.: if *file_roots* is configured as */etc/salt/states/*, the
physical location of the template is
/etc/salt/states/templates/example.jinja

Note:

Under *file_roots*, one can also add:
/etc/salt/templates, define the template file under the
path: */etc/salt/templates/example.jinja* and call using:
salt://example.jinja

Configuration management

Remote templates

Yes, they can also be elsewhere.
Available options: *salt://*, *ftp://*, *http://*, *https://*,
version control, cloud storage providers etc.

```
$ sudo salt -G 'os:ios' net.load_template http://bit.ly/2gKOj20 peers="['172.17.17.1', '172.17.17.2']"
```

Matches all
devices running
IOS

Loads external template
from <http://bit.ly/2gKOj20>
which shortens the link to
the NAPALM native template for IOS.

Configuration management

Advanced templating: reusing existing data (1)

```
{%- set arp_output = salt.net.arp() -%}  
{%- set arp_table = arp_output['out'] -%}  
  
{%- if grains.os|lower == 'iosxr' %} {# if the device is a Cisco IOS-XR #}  
    {%- for arp_entry in arp_table %}  
    arp {{ arp_entry['ip'] }} {{ arp_entry['mac'] }} arpa  
    {%- endfor -%}  
{%- elif grains.vendor|lower == 'juniper' %} {# or if the device is a Juniper #}  
    interfaces {  
        {%- for arp_entry in arp_table %}  
        {{ arp_entry['interface'] }} {  
            family inet {  
                address {{ arp_entry['ip'] }} {  
                    arp {{ arp_entry['ip'] }} mac {{ arp_entry['mac'] }};  
                }  
            }  
        }  
        {%- endfor %}  
    }  
{%- endif %}
```

/etc/salt/templates/arp_example.jinja

Retrieving the ARP table using the [net.arp](#) function.

Configuration management

Advanced templating: reusing existing data (1)

```
$ sudo salt edge01.flw01 net.load_template salt://arp_example.jinja
```

```
edge01.flw01:
```

```
-----
```

```
already_configured:
```

```
False
```

```
comment:
```

```
diff:
```

```
[edit interfaces xe-0/0/0 unit 0 family inet]
```

```
+ address 10.10.2.2/32 {
```

```

```
+ }
```

```
+ }
```

```
result:
```

```
True
```

Configuration management

Advanced templating: reusing existing data (2)

/etc/salt/templates/route_example.jinja

```
{%- set route_output = salt.route.show('0.0.0.0/0', 'static') -%}
{%- set default_route = route_output['out'] -%}

{%- if not default_route -%} {# if no default route found in the table #}
    {%- if grains.vendor|lower == 'juniper' -%}
routing-options {
    static {
        route 0.0.0.0/0 next-hop {{ pillar.default_route_nh }};
    }
}
    {%- elif grains.os|lower == 'iosxr' -%}
router static address-family ipv4 unicast 0.0.0.0/0 {{ pillar.default_route_nh }}
    {%- endif %}
{%- endif -%}
```

Retrieving the static route data using the route.show function.

This requires appending a new line in the device pillar:

default_route_nh: 1.2.3.4

Configuration management

Advanced templating: reusing existing data (2)

```
$ sudo salt 'edge01.oua01' net.load_template salt://route_example.jinja debug=True
```

```
edge01.oua01:
```

```
-----
```

```
already_configured:
```

```
False
```

Homework: other simple examples

- Using [postgres.psql_query](#) populate a table in a Postgres database with the network interfaces details (retrieved using [net.interfaces](#))
- Using [bgp.neighbors](#) remove from the BGP config neighbors in *Active* state
- Using [ntp.stats](#), remove unsynchronised NTP peers
- Using [net.environment](#), push high temperature [notifications in Slack](#)

The list can be nearly infinite - depends only on your own use case.

There are thousands of functions already available:

<https://docs.saltstack.com/en/develop/ref/modules/all/index.html>

Note: the examples above are implemented more elegant using states, beacons, reactors, etc.

Advanced topics

States, schedulers, reactors, beacons, API

These are advanced topics, that require the user to read carefully the documentation.

Using these types of modules, one can control the configuration based on events, either external or internal, e.g.:

- BGP neighbor down triggers a BGP configuration change
- Git pull-request merged triggers configuration update
- High temperature alert triggers a notification post in a Slack channel
- ChatOps
- etc.

Advanced topics

State

A state ensures that on the devices you have configured what you expect to be. What's not defined in the pillar, it will be removed; what's not on the device, but it's defined in the pillar, will be added.

Integrated states:

- netntp
- netsnmp
- netusers
- probes
- netconfig (very important; will be added in the next release: [Nitrogen](#))

Advanced topics

State example: update NTP peers (1)

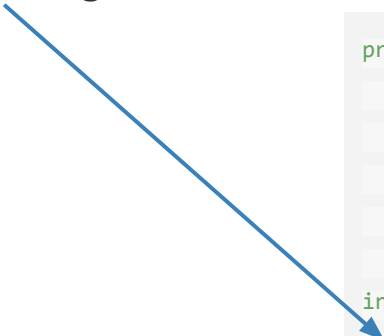

Append directly these lines
in the device pillar, or define
in external file and include:

/etc/salt/pillar/ntp_config.sls

```
ntp.peers:
  - 10.10.1.1
  - 10.10.2.2
ntp.servers:
  - 172.17.17.1
  - 172.17.19.1
```

/etc/salt/pillar/device1.sls

```
proxy:
  proxytype: napalm
  driver: junos
  host: hostname_or_ip_address
  username: my_username
  passwd: my_password
include:
  - ntp_config
```

Better to use the *include*, as
multiple devices can have
the same NTP peers etc.

When including, strip the *.sls*
extension!

Advanced topics

State example: update NTP peers (1)

As configured under *file_roots*

/etc/salt/states/router/ntp.sls

```
{% set ntp_peers = pillar.get('ntp.peers', []) -%}  
{% set ntp_servers = pillar.get('ntp.servers', []) -%}
```

Take the NTP peers/servers
from the pillar (earlier defined)

```
update_my_ntp_config:
```

```
  netntp.managed:
```

```
    - peers: {{ ntp_peers | json() }}  
    - servers: {{ ntp_servers | json() }}
```

Pass them as state arguments

Best practice:

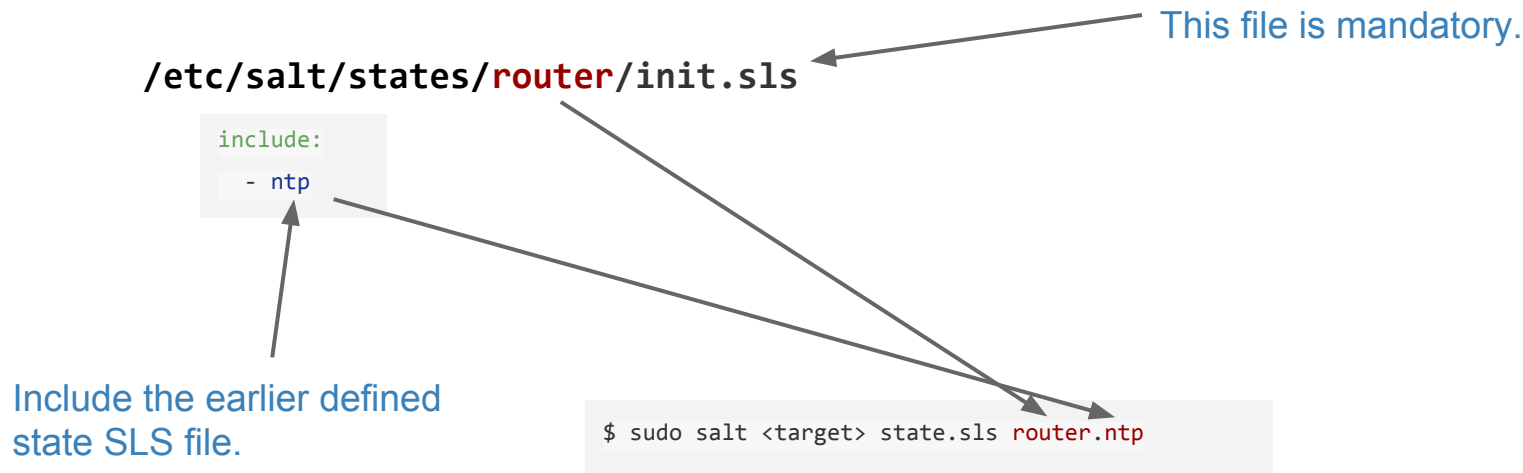

*Although not mandatory, use
the **json()** filter to explicitly
serialize objects.*

This is the state virtualname, more doc:

<https://docs.saltstack.com/en/latest/ref/states/all/salt.states.netntp.html>

Advanced topics

State example: update NTP peers (3)

Advanced topics

State output example: update NTP peers (3)

```
$ sudo salt 'edge01.jnb01' state.sls router.ntp
edge01.jnb01:
-----
          ID: update_my_ntp_config
      Function: netntp.managed
         Result: True
        Started: 09:50:41.228728
       Duration: 16813.319 ms
        Changes:
                -----
                peers:
                -----
                removed:
                - 10.10.1.1
                servers:
                -----
                added:
                - 172.17.17.1
                - 172.17.19.1

Summary for edge01.jnb01
-----
Succeeded: 1 (changed=1)
Failed:    0
-----

Total states run:    1
```

Advanced topics

Schedule a state

Ensure the configuration is consistent, without running commands manually.

/etc/salt/proxy

```
schedule:
  keep_ntp_config_updated:
    function: state.sls
    args: router.ntp
    days: 1
```

The previous command will be executed automatically every day and ensures the NTP config is as expected.

Advanced topics

Salt event system

Salt is a [data driven system](#). Each action (job) performed (manually from the CLI or automatically by the system) is uniquely identified and has an identification tag:

```
$ sudo salt-run state.event pretty=True
salt/job/20170110130619367337/new {
  "_stamp": "2017-01-10T13:06:19.367929",
  "arg": [],
  "fun": "probes.results",
  "jid": "20170110130619367337",
  "minions": [
    "edge01.bjm01"
  ],
  "tgt": "edge01.bjm01",
  "tgt_type": "glob",
  "user": "mircea"
}
```

Unique job tag

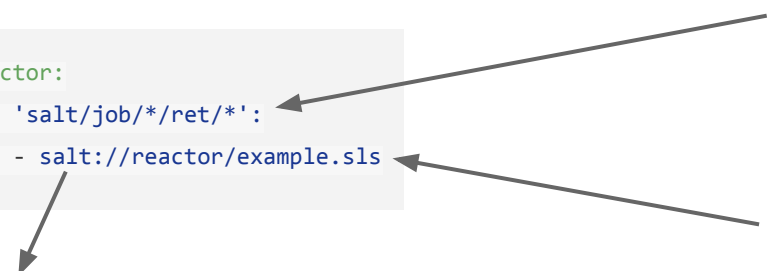

Advanced topics

Reactor

Using the job tags, you can identify events (triggers) and react (action):

/etc/salt/master

```
reactor:  
  - 'salt/job/*/ret/*':  
    - salt://reactor/example.sls
```

A diagram with two arrows. One arrow points from the regular expression 'salt/job/*/ret/*' in the configuration to the explanatory text on the right. The other arrow points from the file path 'salt://reactor/example.sls' in the configuration to the file path shown below.

Unique job tags (regular expression): in this example will match any job returns

When this event occurs, execute this reactor descriptor.

/etc/salt/states/reactor/example.sls

```
invoke_orchestrate_file:  
  runner.state.orchestrate:  
    - mods: orch.do_complex_thing  
    - pillar:  
      event_tag: {{ tag }}  
      event_data: {{ data | json() }}
```

Advanced topics

Beacon

Beacons let you use the Salt event system to monitor non-Salt processes.

/etc/salt/proxy

```
beacons:  
  inotify:  
    /etc/salt/pillar/ntp_config.sls:  
      mask:  
        - modify  
      disable_during_state_run: True
```

Will fire an event when
updating
/etc/salt/pillar/ntp_config.sls
(using the same example as in
slides #52-#54)

Advanced topics

Beacon event tag example

This event is fired when a change is made and saved to `/etc/salt/pillar/ntp_config.sls`:

```
salt/beacon/device1/inotify//etc/salt/pillar/ntp_config.sls {
  "_stamp": "2017-01-09T15:59:37.972753",
  "data": {
    "change": "IN_IGNORED",
    "id": "device1",
    "path": "/etc/salt/pillar/ntp_config.sls"
  },
  "tag": "salt/beacon/device1/inotify//etc/salt/pillar/ntp_config.sls"
}
```

Using the reactor system, one can match these event tags and take actions when they happen.

Advanced topics

Beacon event tag example

React when the `/etc/salt/pillar/ntp_config.sls` is changed

/etc/salt/master

```
reactor:  
  - 'salt/beacon/*/inotify//etc/salt/pillar/ntp_config.sls':  
    - salt://reactor/run_ntp_state_when_file_changed.sls
```

/etc/salt/states/reactor/run_ntp_state_when_file_changed.sls

```
run_ntp_state:  
  local.state.sls:  
    - tgt: {{ data['id'] }}  
    - arg:  
      - router.ntp
```

This is how the reactor system knows that a state execution is required.

Run the state against the minion ID that triggered the event

Run the ntp state defined earlier.

Advanced topics

Beacon event tag example

... and that's it!

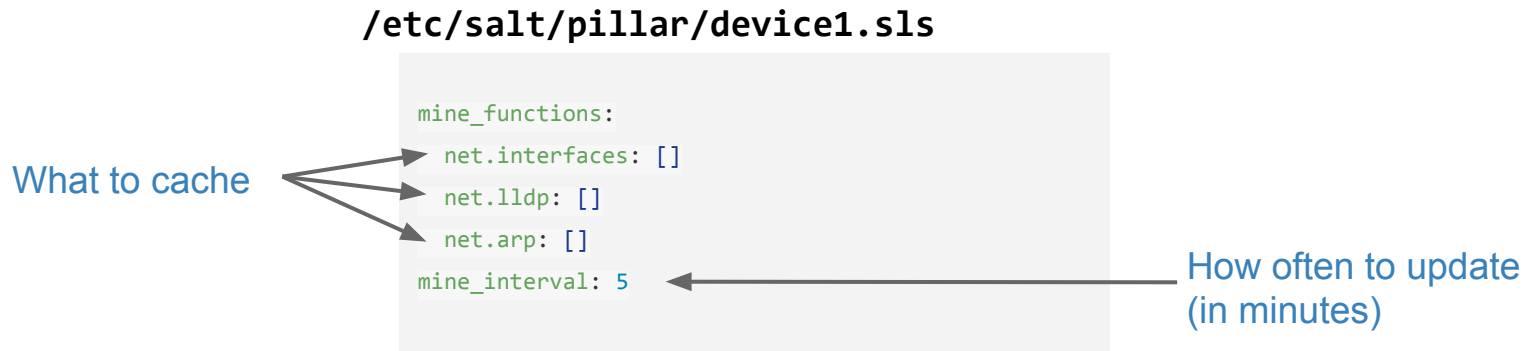

From now on, whenever you update */etc/salt/pillar/ntp_config.sls*,
it will automatically update your routers' config.

And you maintain entities of data, not pseudo-formatted text files,
regardless on the device vendor.

Advanced topics

Mine

Embedded caching

Read more: <https://docs.saltstack.com/en/latest/topics/mine/>

Advanced topics

The Salt API

You can also execute commands remotely, via HTTPS

Easy to setup, easy to use

/etc/salt/master

```
rest_cherry.py:  
  port: 8001  
  ssl_crt: /etc/nginx/ssl/my_certificate.pem  
  ssl_key: /etc/nginx/ssl/my_key.key
```

```
curl -sSk  
https://salt-master-ns-or-ip:8001/run \  
-H 'Content-type: application/json' \  
-d ' [{  
    "client": "local",  
    "tgt": "<target>",  
    "fun": "net.arps",  
    "username": "my username",  
    "password": "my password",  
    "eauth": "pam"  
}] '
```

More advanced topics

- Orchestration: define complex workflows
<https://docs.saltstack.com/en/latest/topics/orchestrate/index.html>
- Publish events to external services (e.g.: logstash, hipchat)
<https://docs.saltstack.com/en/develop/ref/engines/all/index.html>
- Pillar: load data from external services, not just static
<https://docs.saltstack.com/en/develop/ref/pillar/all/>
- Custom authentication methods for the minions
<https://docs.saltstack.com/en/develop/ref/auth/all/index.html>
- Forward outputs in external data systems on runtime
<https://docs.saltstack.com/en/develop/ref/returners/all/index.html>

Real world example:
Cloudflare's self-resilient network

Monitoring carriers (transit providers)

```
mircea@re0.edge01.iad01> show configuration services rpm | display set | match 1299 | match probe-type
set services rpm probe transit test t-edge01.scl01-1299-12956-4 probe-type icmp-ping
set services rpm probe transit test t-edge01.eze01-1299-6762-4 probe-type icmp-ping
set services rpm probe transit test t-edge01.lax01-1299-1299-4 probe-type icmp-ping
set services rpm probe transit test t-edge01.eze01-1299-12956-4 probe-type icmp-ping
set services rpm probe transit test t-edge01.mia01-1299-1299-4 probe-type icmp-ping
set services rpm probe transit test t-edge01.lhr01-1299-1299-4 probe-type icmp-ping
set services rpm probe transit test t-edge01.ams01-1299-1299-4 probe-type icmp-ping
set services rpm probe transit test t-edge01.fra03-1299-1299-4 probe-type icmp-ping
set services rpm probe transit test t-edge01.dfw01-1299-1299-4 probe-type icmp-ping
set services rpm probe transit test t-edge01.sea01-1299-1299-4 probe-type icmp-ping
```

JunOS: RPM

IOS-XR: ISPLA

http://www.cisco.com/c/en/us/td/docs/ios/ipsla/command/reference/sla_book/sla_02.html

How many probes?

```
$ sudo salt-run transits.probes show_count=True
```

```
Generated 7248 probes.
```

Generated using:

- [net.ipaddrs](#)
- [net.interfaces](#)
- [bgp.neighbors](#)
- [bgp.config](#)

All integrated by default in SaltStack.

How are they installed?

```
$ cat /etc/salt/pillar/probes_edge01_dfw01.sls
probes.config:
  transit:
    t-edge01.sjc01-1299-1299-4:
      source: 1.2.3.4
      target: 5.6.7.8
    t-edge01.den01-1299-1299-4:
      source: 10.11.12.13
      target: 14.15.16.17
    t-edge01.den01-174-174-4:
